

## Goldenrod

In the fall, few wildflowers put on such a brilliant show as goldenrods. There are many species of goldenrod, all native North American perennials with large clusters of small yellow flowers that appear from the end of summer until frost. They are often mistakenly blamed for causing hay fever, probably because they are so visible and abundant, but the real culprit is ragweed.

In the garden clump-forming goldenrods are preferable to those that spread by rhizomes. There are many types, varying in height from 1-6 feet tall. Some good choices include 'Cloth of Gold', 'Crown of Rays', 'Fireworks', 'Golden Baby', 'Golden Fleece' and the species *Solidago rigida* and *S. speciosa*. Plant in full sun or partial shade. Goldenrod is drought tolerant once established and it is not a favored food of deer.
